Laboratory 5 - Indexes

Work on 3 tables of the form Ta(aid, a2, ...), Tb(bid, b2, ...), Tc(cid, aid, bid, ...), where:

- aid, bid, cid, a2, b2 are integers;
- the primary keys are underlined;
- a2 is UNIQUE in Ta;
- aid and bid are foreign keys in Tc, referencing the corresponding primary keys in Ta and Tb, respectively.

In this laboratory you should create 3 tables that satisfy the conditions given in the request of your homework.

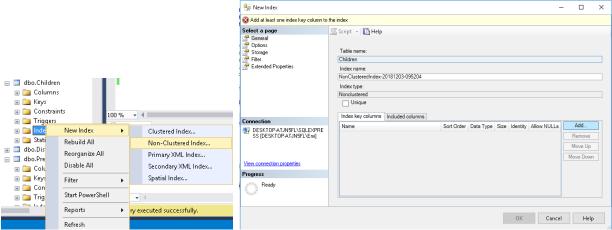

Here, I consider the following database (please don't use this database/tables ②):

```
create database Lab5 IE
go
                                                                                      Presents
use Lab5 IE
                                                              Distributions
                                                              7 Did
                                                                                        PName
CREATE TABLE Children(-- Ta
                                                                                        Color
                                                                Pid
Cid INT PRIMARY KEY IDENTITY, -- aid
                                                                                        Price
Name VARCHAR(50),
Age INT, -- a2
WishId INT UNIQUE
                                                              Children
                                                               7 Cid
CREATE TABLE Presents(-- Tb
Pid INT PRIMARY KEY IDENTITY, -- bid
PName VARCHAR(50),
                                                                Wishld
Color VARCHAR(50),
Price INT-- b2
                                                              iii Results
                                                                        눩 Messages
                                                                       Name
                                                                             Age
                                                                                  Wishld
CREATE TABLE Distributions(-- Tc

Cid INT FOREIGN KEY REFERENCES Children(Cid), -- aid
                                                                       PName
                                                                              Color
                                                                                    Price
Pid INT FOREIGN KEY REFERENCES Presents(Pid) -- bid
select * from Children
                                                                           Pid
                                                                   Did
                                                                       Cid
select * from Presents
select * from Distributions
```

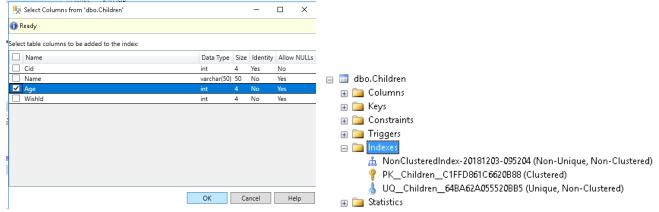

- a. Write 5 queries on Ta such that their corresponding execution plans contain the following operators:
 - clustered index scan
 - clustered index seek;
 - nonclustered index scan;
 - nonclustered index seek;
 - key lookup.

To create a *nonclustered index* by using Object Explorer

- Choose the database -> Tables (folder) -> expand the table that will be used to create a non-clustered index -> Right-click the Indexes folder -> New Index -> select Non-Clustered Index...

- In the New Index dialog box -> General page -> Index name box (=enter the name of the new index)
- Under Index key columns -> click Add... -> In the Select Columns from table_name dialog box -> select the check box(es) of the table column(s) to be added to the nonclustered index ->Ok -> Ok.

To create a nonclustered index on a table by using Transact-SQL

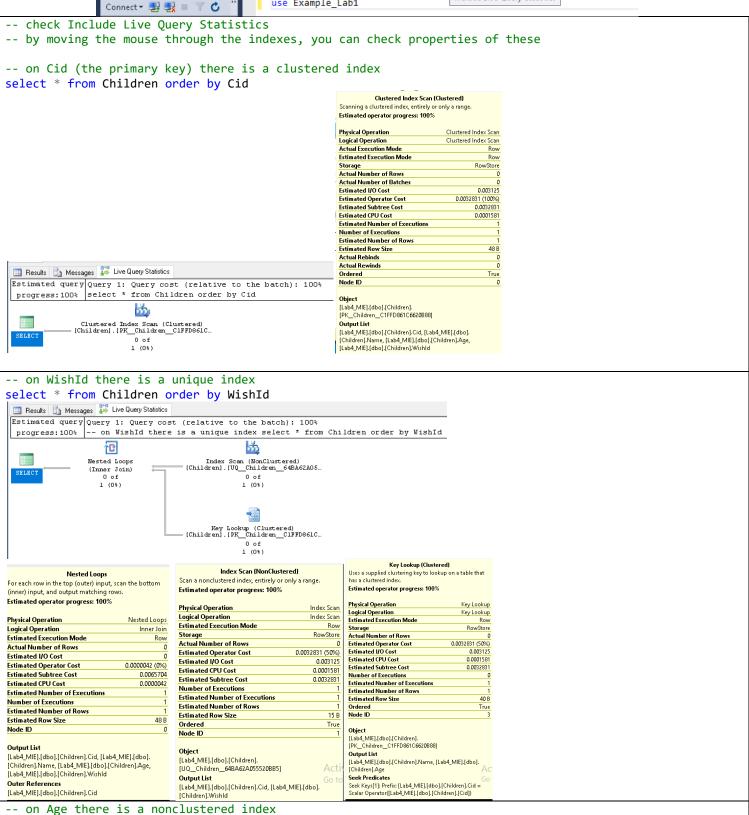

- Choose the database -> New Query -> write the code -> Execute

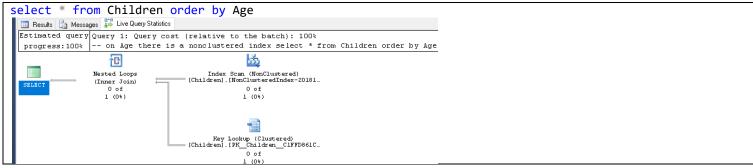

```
-- Find an existing index named N idx Color and delete it if found.
IF EXISTS (SELECT name FROM sys.indexes WHERE name = N'N idx Color')
    DROP INDEX N idx Color ON Presents;
G0
-- Create a nonclustered index called N_idx_Color on the Presents table using the Color column.
CREATE NONCLUSTERED INDEX N_idx_Color ON Presents(Color);
G0
                                                         dbo.Presents
                                                           🖪 🛅 Columns
                                                           🖪 🛅 Constraints
                                                           🖃 🛅 Indexes
                                                               M_idx_Color (Non-Unique, Non-Clustered)
                                                               PK_Presents_C5705938BE7CA46B (Clustered)
                   Command(s) completed successfully.
```

Check the Clustered/NonClustered indexes

- check **Include Live Query Statistics** - when a query is open (and the properties can be check for the exeuted query). After an operation (update, order by, ...), the order of the records is modified. For example, the indexes become unordered (1,2,3 -> 3,1,2). To choose the best index you can work with Include Live Query Statistics.

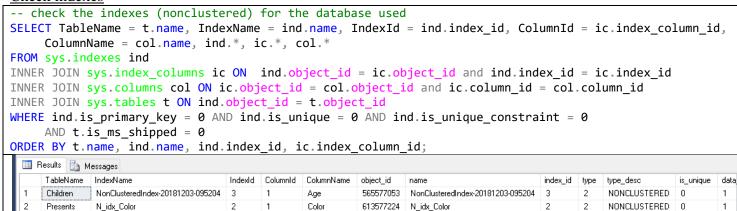

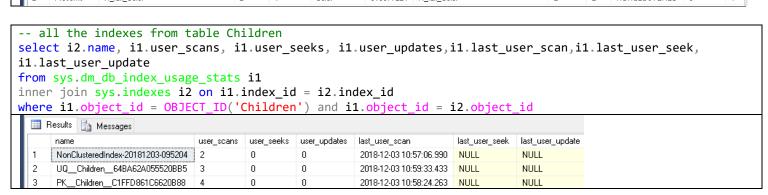

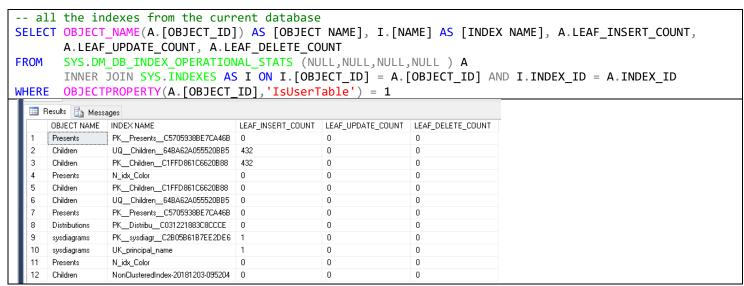

Index on primary key = it is created automatically when the primary key is created = index clustered Index on unique key = it is created automatically when the unique constraint is created = index nonclustered

Check indexes

b. Write a query on table Tb with a WHERE clause of the form *WHERE b2 = value* and analyze its execution plan. Create a nonclustered index that can speed up the query. Recheck the query's execution plan (operators, SELECT's *estimated subtree cost*).

```
-- Find an existing index named N_idx_Price and delete it if found.

IF EXISTS (SELECT name FROM sys.indexes WHERE name = N'N_idx_Price')

DROP INDEX N_idx_Price ON Presents;

GO
-- Create a nonclustered index called N_idx_Price on the Presents table using the Price column.

CREATE NONCLUSTERED INDEX N_idx_Price ON Presents(Price);

GO

select * from Presents where Price=8

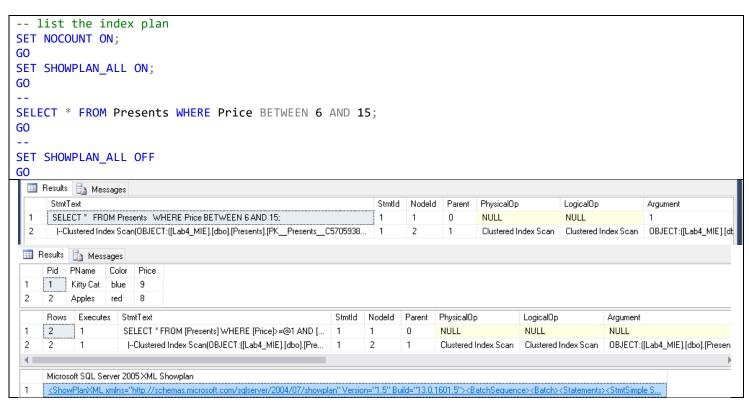

Results Messages Live Query Statistics

Estimated query Query 1: Query cost (relative to the batch): 100%

progress:100% SELECT * FROM [Presents] WHERE [Price]=01

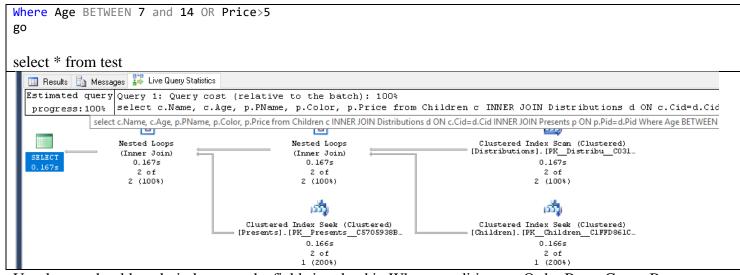

Clustered Index Scan (Clustered)

[Presents].[PK_Presents_CS705938B_
1 of
1 (1004)
```

c. Create a view that joins at least 2 tables. Check whether existing indexes are helpful by using *dynamic management* objects; if this is not the case, reassess existing indexes / examine the cardinality of the tables.

```
create view test
as
select c.Name, c.Age, p.PName, p.Color, p.Price
from Children c INNER JOIN Distributions d ON c.Cid=d.Cid
INNER JOIN Presents p ON p.Pid=d.Pid
```

Usualy you should apply indexes on the fields involved in Where conditions or Order By or Group By.

```
-- Find an existing index named N idx Name and delete it if found.
IF EXISTS (SELECT name FROM sys.indexes WHERE name = N'N idx Name')
     DROP INDEX N idx Name ON Children;
GO.
-- Create a nonclustered index called N idx Color on the Presents table using the Color column.
CREATE NONCLUSTERED INDEX N idx Name ON Children(Name);
G<sub>0</sub>
select c.Name
from Children c INNER JOIN Distributions d ON c.Cid=d.Cid
INNER JOIN Presents p ON p.Pid=d.Pid
Where Age BETWEEN 7 and 14 OR Price>5
